Data Guide

Wireless made simple®

Warning: Linx radio frequency ("RF") products may be used to control machinery or devices remotely, including machinery or devices that can cause death, bodily injuries, and/or property damage if improperly or inadvertently triggered, particularly in industrial settings or other applications implicating life-safety concerns. No Linx Technologies product is intended for use in any application without redundancies where the safety of life or property is at risk.

The customers and users of devices and machinery controlled with RF products must understand and must use all appropriate safety procedures in connection with the devices, including without limitation, using appropriate safety procedures to prevent inadvertent triggering by the user of the device and using appropriate security codes to prevent triggering of the remote controlled machine or device by users of other remote controllers.

Do not use this or any Linx product to trigger an action directly from the data line or RSSI lines without a protocol or encoder/decoder to validate the data. Without validation, any signal from another unrelated transmitter in the environment received by the module could inadvertently trigger the action.

All RF products are susceptible to RF interference that can prevent communication. RF products without frequency agility or hopping implemented are more subject to interference. This module does not have a frequency hopping protocol built in.

Do not use any Linx product over the limits in this data guide. Excessive voltage or extended operation at the maximum voltage could cause product failure. Exceeding the reflow temperature profile could cause product failure which is not immediately evident.

Do not make any physical or electrical modifications to any Linx product. This will void the warranty and regulatory and UL certifications and may cause product failure which is not immediately evident.

Ordering Information

Electrical Specifications

ES Series Receiver Specifications						
Parameter	**Symbol**	**Min.**	**Typ.**	**Max.**	**Units**	**Notes**
Power Supply						
Operating Voltage	V_{CC}	4.5	5.0	5.5	VDC	
Supply Current	I_{CC}	5.5	6.0	6.5	mA	
Power-Down Current	I_{PDN}		50.0		µA	4
Receiver Section						
Receive Frequency	F_C					
RXM-869-ES			869.85		MHz	
RXM-916-ES			916.48		MHz	
Center Frequency Accuracy		–60		+60	kHz	
LO Frequency						
RXM-869-ES			859.15		MHz	
RXM-916-ES			905.78		MHz	
IF Frequency	F_{IF}		10.7		MHz	
Spurious Emissions			–75	–50	dBm	1
Receiver Sensitivity		–92	–97	–102	dBm	2
Noise Bandwidth	N_{3dB}		280		kHz	
Audio Bandwidth		20		28,000	Hz	3,4
Audio Output Level			360		mV_{P-P}	4,5
Data Rate		200		56,000	bps	4

Absolute Maximum Ratings

Absolute Maximum Ratings				
Supply Voltage V_{cc}	–0.3	to	+5.5	VDC
Any Input or Output Pin	–0.3	to	V_{CC} + 0.3	VDC
Operating Temperature	0	to	+70	ºC
Storage Temperature	–40	to	+125	ºC
Soldering Temperature	260ºC for 15 seconds			

Exceeding any of the limits of this section may lead to permanent damage to the device. Furthermore, extended operation at these maximum ratings may reduce the life of this device.

Module Description

The ES Series receiver module is a single-channel receiver designed for the wireless reception of digital or analog information over distances of up to 1,000 feet outdoors and up to 500 feet indoors. It is based on a high-performance, synthesized, single conversion, superhet architecture. FM / FSK modulation and SAW filtering are utilized to provide performance and noise immunity that are superior to AM-based solutions. The ES series is incredibly compact and cost effective when compared with other FM / FSK devices. Best of all, it is packed with many useful features, offering a great deal of design flexibility.

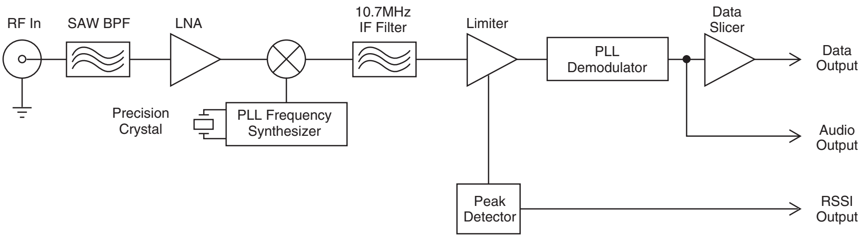

Figure 11: ES Series Receiver Block Diagram

Theory of Operation

The receiver operates in a single conversion superhet configuration, with an IF of 10.7MHz and a baseband analog bandwidth of 28kHz. It is capable of receiving a signal as low as –97dBm (typical). The signal is filtered at the front end by a SAW band-pass filter. The filtered signal is then amplified and downconverted to the 10.7MHz IF by mixing it with a LO frequency generated by a PLL-locked VCO. The 10.7MHz IF is then amplified and filtered. Finally, a PLL demodulator is used to recover the baseband analog signal from the carrier. This analog signal is low-pass filtered and then output on the AUDIO line.

The analog output can be individual frequencies or complex waveforms, such as voice or music. The AUDIO line can also be used to recover unsquared data in instances where a designer wishes to use an external data slicer.

The ES receiver also features a high-performance on-board data slicer for recovery of data transmission. Its output is internally derived from the filtered analog baseband, which is squared and made externally available on the DATA line. The data slicer is capable of recreating squared waveforms from 100Hz to 28kHz, giving a data rate bandwidth of 200bps to 56kbps.

Using the RSSI Line

The receiver's Received Signal Strength Indicator (RSSI) line serves a variety of uses. The RSSI line has a dynamic range of 60dB (typical) and outputs a voltage proportional to the incoming signal strength. A graph of the RSSI line's characteristics appears in the Typical Performance Graphs section. The RSSI levels and dynamic range vary slightly from part to part. It is important to remember that the RSSI output indicates the strength of any in-band RF energy and not necessarily just that from the intended transmitter; therefore, it should only be used to qualify the level and presence of a signal.

The RSSI output can be used to create external squelch circuits. It can be utilized during testing or even as a product feature to assess interference and channel quality by looking at the voltage level with all intended transmitters off. The RSSI output can also be used in direction-finding applications although there are many potential perils to consider in such systems. Finally, it can be used to save system power by "waking up" external circuitry when a transmission is received or crosses a certain threshold. The RSSI output feature adds tremendous versatility for the creative designer.

Using the ES Series Receiver for Analog Applications

The ES Series is an excellent choice for sending a wide range of analog information, including audio. The ability of the ES to receive combinations of analog and digital signals also opens new areas of opportunity for creative product design.

The AUDIO line should be buffered and filtered to obtain maximum signal quality. This is particularly important because the audio output is AC-coupled and any DC loading causes errors in the data slicer since data is derived from the audio voltage. For voice, a 3–4kHz low-pass filter is often employed. For broader-range sources, such as music, a 12–20kHz cutoff is more appropriate. When only sending audio, the DATA line should be pulled to V_{CC} to reduce noise resulting from the data slicer switching.

The Signal-to-Noise Ratio (SNR) of the audio depends on the bandwidth selected. The higher the SNR, the less hiss there is in the background. For the best SNR, choose the lowest filter cutoff appropriate for the intended signal. For applications that require true high fidelity, audio RF links designed expressly for this purpose may prove to be a more appropriate solution; however, a compandor may also be used with the ES Series higher than the reference voltage before switching on. This prevents low amplitude noise from causing the data line to oscillate. Strong signals can still get through, so it is a good idea to have a noise tolerant protocol.

Creating a circuit that has additional hysteresis characteristics is very basic and requires very few parts thanks to the A REF line. All you need are a couple resistors to provide some isolation for the AUDIO and A REF lines, a large feedback resistor, a pull-up resistor, and an open collector comparator.

The RSSI and A REF lines allow a wide variety of squelch circuits to be implemented. One such possibility is the circuit in Figure 13, which is used on the ES Series Master Development System, and may be employed for audio or data squelching. It is ultimately the responsibility of the designer to determine what, if any, circuit would be most appropriate for the needs of the product.

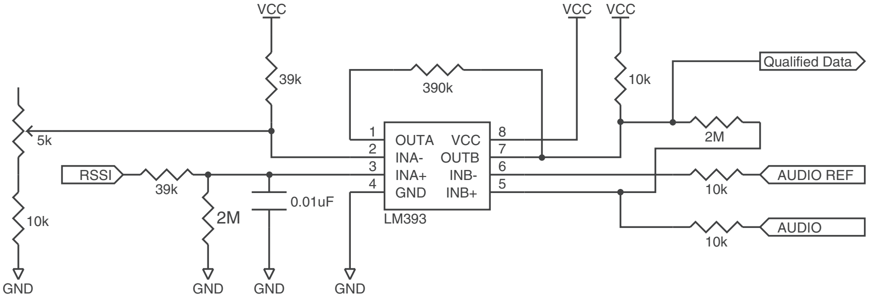

Figure 13: ES Series Receiver Squelch / Hysteresis Circuit

Data squelching in the circuit above is accomplished by comparing the RSSI voltage to a voltage reference (typically a voltage divider) with an open collector style comparator. When the voltage from the RSSI becomes lower than the voltage reference, the comparator output is pulled to GND. This is useful because this output can be used to disable the data-slicer circuit either when the receiver is out of range or the transmitter is turned off.

The squelch threshold is normally set as low as possible to ensure maximum sensitivity and range. It is important to recognize that in many actual use environments, ambient noise and interference may enter the receiver at levels well above the squelch threshold. For this reason, it is always recommended that the product's protocol be structured to allow for the possibility of hashing even when an external squelch circuit is employed.

Interference Considerations

The RF spectrum is crowded and the potential for conflict with unwanted sources of RF is very real. While all RF products are at risk from interference, its effects can be minimized by better understanding its characteristics.

Interference may come from internal or external sources. The first step is to eliminate interference from noise sources on the board. This means paying careful attention to layout, grounding, filtering and bypassing in order to eliminate all radiated and conducted interference paths. For many products, this is straightforward; however, products containing components such as switching power supplies, motors, crystals and other potential sources of noise must be approached with care. Comparing your own design with a Linx evaluation board can help to determine if and at what level design-specific interference is present.

External interference can manifest itself in a variety of ways. Low-level interference produces noise and hashing on the output and reduces the link's overall range.

High-level interference is caused by nearby products sharing the same frequency or from near-band high-power devices. It can even come from your own products if more than one transmitter is active in the same area. It is important to remember that only one transmitter at a time can occupy a frequency, regardless of the coding of the transmitted signal. This type of interference is less common than those mentioned previously, but in severe cases it can prevent all useful function of the affected device.

Although technically not interference, multipath is also a factor to be understood. Multipath is a term used to refer to the signal cancellation effects that occur when RF waves arrive at the receiver in different phase relationships. This effect is a particularly significant factor in interior environments where objects provide many different signal reflection paths. Multipath cancellation results in lowered signal levels at the receiver and shorter useful distances for the link.

Make sure internal wiring is routed away from the module and antenna and is secured to prevent displacement.

Do not route PCB traces directly under the module. There should not be any copper or traces under the module on the same layer as the module, just bare PCB. The underside of the module has traces and vias that could short or couple to traces on the product's circuit board.

The Pad Layout section shows a typical PCB footprint for the module. A ground plane (as large and uninterrupted as possible) should be placed on a lower layer of your PC board opposite the module. This plane is essential for creating a low impedance return for ground and consistent stripline performance.

Use care in routing the RF trace between the module and the antenna or connector. Keep the trace as short as possible. Do not pass it under the module or any other component. Do not route the antenna trace on multiple PCB layers as vias add inductance. Vias are acceptable for tying together ground layers and component grounds and should be used in multiples.

Each of the module's ground pins should have short traces tying immediately to the ground plane through a via.

Bypass caps should be low ESR ceramic types and located directly adjacent to the pin they are serving.

A 50-ohm coax should be used for connection to an external antenna. A 50-ohm transmission line, such as a microstrip, stripline or coplanar waveguide should be used for routing RF on the PCB. The Microstrip Details section provides additional information.

In some instances, a designer may wish to encapsulate or "pot" the product. There are a wide variety of potting compounds with varying dielectric properties. Since such compounds can considerably impact RF performance and the ability to rework or service the product, it is the responsibility of the designer to evaluate and qualify the impact and suitability of such materials.

Production Guidelines

The module is housed in a hybrid SMD package that supports hand and automated assembly techniques. Since the modules contain discrete components internally, the assembly procedures are critical to ensuring the reliable function of the modules. The following procedures should be reviewed with and practiced by all assembly personnel.

Hand Assembly

Pads located on the bottom of the module are the primary mounting surface (Figure 18). Since these pads are inaccessible during mounting, castellations that run up the side of the module have been provided to facilitate solder wicking to the module's underside. This allows for very quick hand soldering for prototyping and small volume production. If the recommended pad guidelines have been followed, the pads will protrude slightly past the edge of the module. Use a fine soldering tip to heat the board pad and the castellation, then introduce solder to the pad at the module's edge. The solder will wick underneath the module, providing reliable attachment. Tack one module corner first and then work around the device, taking care not to exceed the times in Figure 19.

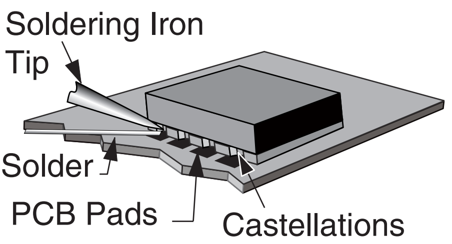

Figure 18: Soldering Technique

Warning: Pay attention to the absolute maximum solder times.

Absolute Maximum Solder Times
Hand Solder Temperature: +225ºC for 10 seconds
Recommended Solder Melting Point: +180ºC
Reflow Oven: +255ºC max (see Figure 20)

Figure 19: Absolute Maximum Solder Times

Automated Assembly

For high-volume assembly, the modules are generally auto-placed. The modules have been designed to maintain compatibility with reflow processing techniques; however, due to their hybrid nature, certain aspects of the assembly process are far more critical than for other component types. Following are brief discussions of the three primary areas where caution must be observed.

Helpful Application Notes From Linx

It is not the intention of this manual to address in depth many of the issues that should be considered to ensure that the modules function correctly and deliver the maximum possible performance. As you proceed with your design, you may wish to obtain one or more of the following application notes which address in depth key areas of RF design and application of Linx products. These application notes are available online at www.linxtechnologies.com or by contacting Linx.

General Antenna Rules

The following general rules should help in maximizing antenna performance.

1. Proximity to objects such as a user's hand, body or metal objects will cause an antenna to detune. For this reason, the antenna shaft and tip should be positioned as far away from such objects as possible.

2. Optimum performance is obtained from a ¼- or ½-wave straight whip mounted at a right angle to the ground plane (Figure 23). In many cases, this isn't desirable for practical or ergonomic reasons, thus, an alternative antenna style such as a helical, loop or patch may be utilized and the corresponding sacrifice in performance accepted.

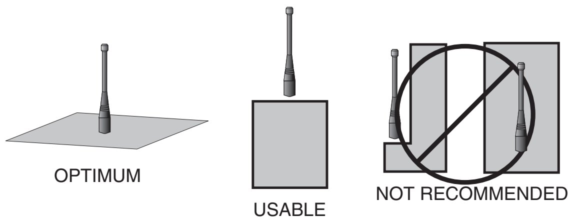

Figure 23: Ground Plane Orientation

3. If an internal antenna is to be used, keep it away from other metal components, particularly large items like transformers, batteries, PCB tracks and ground planes. In many cases, the space around the antenna is as important as the antenna itself. Objects in close proximity to the antenna can cause direct detuning, while those farther away will alter the antenna's symmetry.

4. In many antenna designs, particularly ¼-wave whips, the ground plane acts as a counterpoise, forming, in essence, a ½-wave dipole (Figure 24). For this reason, adequate ground plane area is essential. The ground plane can be a metal case or ground-fill areas on a circuit board. Ideally, it should have a surface area less than or equal to the overall length of the ¼-wave radiating element. This is often not practical due to size and configuration constraints. In these instances, a designer must make the best use of the area available to create as much ground

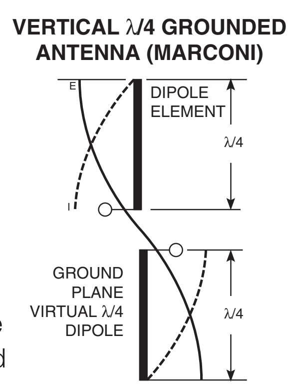

Figure 24: Dipole Antenna

Common Antenna Styles

There are hundreds of antenna styles and variations that can be employed with Linx RF modules. Following is a brief discussion of the styles most commonly utilized. Additional antenna information can be found in Linx Application Notes AN-00100, AN-00140, AN-00500 and AN-00501. Linx antennas and connectors offer outstanding performance at a low price.

Whip Style

A whip style antenna (Figure 26) provides outstanding overall performance and stability. A low-cost whip can be easily fabricated from a wire or rod, but most designers opt for the consistent performance and cosmetic appeal of a professionally-made model. To meet this need, Linx offers a wide variety of straight and reduced height whip style antennas in permanent and connectorized mounting styles.

Figure 26: Whip Style Antennas

The wavelength of the operational frequency determines an antenna's overall length. Since a full wavelength is often quite long, a partial ½- or ¼-wave antenna is normally employed. Its size and natural radiation resistance make it well matched to Linx modules. The proper length for a straight ¼-wave can be easily determined using the formula in Figure 27. It is also possible to reduce the overall height of the antenna by using a helical winding. This reduces the antenna's bandwidth but is a great way to minimize the antenna's physical size for compact applications. This also means that the physical appearance is not always an indicator of the antenna's frequency.

$$L = \frac{234}{F_{MHz}}$$

Figure 27:
L = length in feet of quarter-wave length
F = operating frequency in megahertz

Specialty Styles

Linx offers a wide variety of specialized antenna styles (Figure 28). Many of these styles utilize helical elements to reduce the overall antenna size while maintaining reasonable performance. A helical antenna's bandwidth is often quite narrow and the antenna can detune in proximity to other objects, so care must be exercised in layout and placement.

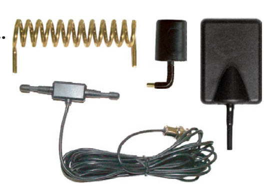

Figure 28: Specialty Style Antennas

Regulatory Considerations

> Note: Linx RF modules are designed as component devices that require external components to function. The purchaser understands that additional approvals may be required prior to the sale or operation of the device, and agrees to utilize the component in keeping with all laws governing its use in the country of operation.

When working with RF, a clear distinction must be made between what is technically possible and what is legally acceptable in the country where operation is intended. Many manufacturers have avoided incorporating RF into their products as a result of uncertainty and even fear of the approval and certification process. Here at Linx, our desire is not only to expedite the design process, but also to assist you in achieving a clear idea of what is involved in obtaining the necessary approvals to legally market a completed product.

For information about regulatory approval, read AN-00142 on the Linx website or call Linx. Linx designs products with worldwide regulatory approval in mind.

In the United States, the approval process is actually quite straightforward. The regulations governing RF devices and the enforcement of them are the responsibility of the Federal Communications Commission (FCC). The regulations are contained in Title 47 of the United States Code of Federal Regulations (CFR). Title 47 is made up of numerous volumes; however, all regulations applicable to this module are contained in Volume 0-19. It is strongly recommended that a copy be obtained from the FCC's website, the Government Printing Office in Washington or from your local government bookstore. Excerpts of applicable sections are included with Linx evaluation kits or may be obtained from the Linx Technologies website, www.linxtechnologies.com. In brief, these rules require that any device that intentionally radiates RF energy be approved, that is, tested for compliance and issued a unique identification number. This is a relatively painless process. Final compliance testing is performed by one of the many independent testing laboratories across the country. Many labs can also provide other certifications that the product may require at the same time, such as UL, CLASS A / B, etc. Once the completed product has passed, an ID number is issued that is to be clearly placed on each product manufactured.
